| | | | | | | | | | |
| | Year 1 Y | ear 2 | Year 3 | Year 4 | Year 5 | Year 6 | Year 7 and beyond | | |

The company has determined the appropriate discount rate for the Nanjing outlet is 6.95% p.a. compounded monthly whilst the discount rate for the Xi'An outlet is 6.90% p.a.

\$745,000

\$320,000

\$450,000

\$680,000

\$795,000

\$1,150,000

\$1,250,000

Using this information answer the following questions:

- a) What is the effective annual compound discount rate of both the Nanjing and Xi'An outlets?
- b) What is the maximum amount that XHZ Ltd should pay for each of the retail outlets?
- c) What constant cash flow each year would give the same price for each of the retail outlets as was calculated in part b)? Which outlet generates the highest equivalent annual cash flow?
- d) Which store should XHZ Ltd purchase if the price of the Nanjing outlet was \$13,500,000 and the price of the Xi'An outlet was \$14,800,000?

Answer: a) Using the effective interest rate equation we get the following discount rates for the two outlets:

```
Nanjing outlet = [1 + (0.0695/12)]^{12} - 1 = 7.18\% p.a.
Xi'An outlet = [1 + (0.0690/365)]^{365} - 1 = 7.14\% p.a.
```

b) The maximum amount that XHZ Ltd would be willing to pay is the present value of the cash flows of the two outlets. This is found by discounting the cash flows by the effective rate determined in part a) of the question. The first step is to find the present value of the perpetuity beginning in year 7 and then discount this value and the years 1 through 6 cash flows as single future values.

Nanjing Outlet:

```
PV_6 = 1,100,000/0.0718 = $15,320,334.26
```

```
PV_0 = 540,000/(1.0718) + 670,000/(1.0718)^2 + 750,000/(1.0718)^3 + 780,000/(1.0718)^4 + 820,000/(1.0718)^5 + 950,000/(1.0718)^6 + 15,320,334.26/(1.0718)^6
= $13,599,858.88
```

So the maximum purchase price of the Nanjing outlet would be \$13,599,858.88

Xi'An Outlet:

```
PV_6 = 1,250,000/0.0714 = $17,507,002.80
```

```
PV_0 = 320,000/(1.0714) + 450,000/(1.0714)^2 + 680,000/(1.0714)^3 + 745,000/(1.0714)^4 + 795,000/(1.0714)^5 + 1,150,000/(1.0714)^6 + 17,507,002.80/(1.0714)^6
= $14,706,924.86
```

So the maximum purchase price of the Xi'An outlet would be \$14,706,924.86

c) The constant cash flow each year would give the same price for each of the retail outlets as was calculated in part b) is a perpetuity calculation.

Nanjing Outlet:

```
$13,599,858.88 = A/0.0718
```

A = \$976,469.87

Xi'An Outlet:

\$14,706,924.86 = A/0.0714

A = \$1,050,074.44

Thus the Xi'An store generates the highest equivalent annual cash flow.

d) Given those purchase prices the 'wealth' created by each outlet would be: Nanjing Outlet:

```
13,599,858.88 - 13,500,000 = 599,858.88
```

Xi'An Outlet:

Answer: \$14,706,924.86 - \$14,800,000 = -\$93,075.14

increase the firm's wealth. **Explanation:** 38) You have just won first division in the State lottery, and have a choice between three 38) alternatives as to how your prize is to be received. You can get \$100,000 now, or \$10,000 per year in perpetuity, or \$50,000 now and \$150,000 at the end of 10 years. If the appropriate discount rate is 12% per annum, which option should you choose? Answer: Calculate the present value of each option, and choose the one with the highest present value. Option 1 has a present value of \$100,000 (given); option 2 has a present value of \$10,000/0.12 = \$83,333; option three has a present value of \$50,000 + $150,000[(1-(1+0.12)^{-10}]/0.12 = 98,300$. Therefore the highest present value, and thus the best option to choose, is option 1: take the \$100,000 today. **Explanation:** 39) You are considering the purchase of new car using a financing arrangement. Under the 39) deal you must make a \$10,000 deposit immediately and then monthly payments of \$800 for a period of 48 months. The monthly payments are made at the end of each month. The interest rate is 12% p.a. compounded monthly. What is the effective cost of the car? Answer: You must make an initial payment of \$10,000 plus a series of annuity payments of \$800 per month for 48 months. The present value of the annuity is: The monthly interest rate will be 12/12 or 1% $800 [1 - (1 + 0.01)^{-48}]/0.01 = $30.379.17$ Therefore the effective cost of the car will be \$30,379.17 + \$10,000 = \$40,379.17**Explanation:** 40) An investor has the possibility to deposit \$500 in one of two potential bank accounts. 40) Account A offers an interest rate of 5% p.a. compounded semi-annually whilst Account B offers an interest rate of 4.9% p.a. compounded quarterly. Which will yield the highest future value? Answer: Determine the effective simple interest equivalent of each accounts interest rate and compare them. Account A is giving the depositor an effective simple interest rate of 5.06% [EAR = $(1 + 0.05/2)^2 - 1$] whilst Account B is offering the depositor an effective interest rate of 4.99% [EAR = $(1 + 0.049/4)^4$ - 1]. Hence Account A will yield the highest future value for the depositor. **Explanation:** TRUE/FALSE. Write 'T' if the statement is true and 'F' if the statement is false.

So XHZ Ltd should purchase the Nanjing store as it is the only one which will

41) The present value of an annuity due is always less than the present value of an otherwise identical

42) The effective rate of interest decreases as the compounding frequency increases.

ordinary annuity.

True

True

False

False

Answer:

Answer:

Explanation:

Explanation:

41)

42)

| 43) An annuity due has cash flows that occur at the end of each period. | 43) |
|--|-----|
| Answer: True Selse Explanation: | |
| 44) A deferred annuity is an annuity due that starts at a date more than one period into the future. | 44) |
| Answer: True Selse Explanation: | |
| 45) The future value compounding formula is $FV = PV(1 + r)n$. | 45) |
| Answer: True False Explanation: | |
| 46) Holding all other factors constant, increasing the frequency of the compounding period will increase the future value of an initial investment. | 46) |
| Answer: True False Explanation: | |
| 47) A perpetuity is an annuity that lasts forever. | 47) |
| Answer: True False | |
| Explanation: | |
| 48) Interest earned on long-term bonds is an example of an annuity. | 48) |
| Answer: True False Explanation: | |
| 49) A bank that offers depositors a 10% p.a. rate compounded semi-annually is using continuous compounding to calculate depositors' interest payments. | 49) |
| Answer: True Selse Explanation: | |
| 50) An ordinary annuity has unequal cash flows. | 50) |
| Answer: True ♥ False Explanation: | |
| 51) The effective simple interest rate will always be higher than the compound interest rate if the compounding interval is greater than one. | 51) |
| Answer: ☑ True False Explanation: | |
| 52) The cash flows of an ordinary annuity occur at the end of each period. | 52) |
| Answer: ☑ True False Explanation: | |
| 53) The amount of interest earned each year does not change when interest is compounded. | 53) |
| Answer: True ♥ False Explanation: | |
| 54) A constant dividend paying share is an example of an ordinary annuity. | 54) |
| Answer: True Selse Explanation: | |

| 55) The future value of a future cash flow will always be lower than the present value if the interest | 55) | |
|--|-----|--|
| rate used is anything other than zero. | | |

Answer: True False

30) A

31) B

32) D

33) B

34) D 35) B

36) By definition a perpetual stream of cash flows continues indefinitely and hence has no future value. We can however determine the value of the perpetuity at any point in the future since its future value will simply be the present value of the remaining cash flows beyond that point.

37) a) Using the effective interest rate equation we get the following discount rates for the two outlets:

```
Nanjing outlet = [1 + (0.0695/12)]^{12} - 1 = 7.18\% p.a.
```

 $Xi'An outlet = [1 + (0.0690/365)]^{365} - 1 = 7.14\% p.a.$

b) The maximum amount that XHZ Ltd would be willing to pay is the present value of the cash flows of the two outlets. This is found by discounting the cash flows by the effective rate determined in part a) of the question. The first step is to find the present value of the perpetuity beginning in year 7 and then discount this value and the years 1 through 6 cash flows as single future values.

Nanjing Outlet:

```
PV_6 = 1,100,000/0.0718 = $15,320,334.26
```

$$PV_0 = 540,000/(1.0718) + 670,000/(1.0718)^2 + 750,000/(1.0718)^3 + 780,000/(1.0718)^4 + 820,000/(1.0718)^5 + 780,000/(1.0718)^4 + 820,000/(1.0718)^4 + 820,000/(1.0718)^5 + 820,000/(1.0718)^6 + 82$$

Answer Key Testname: C2

```
950,000/(1.0718)<sup>6</sup> + 15,320,334.26/(1.0718)<sup>6</sup> = $13,599,858.88
```

So the maximum purchase price of the Nanjing outlet would be \$13,599,858.88

Xi'An Outlet:

 $PV_6 = 1,250,000/0.0714 = $17,507,002.80$

 $PV_0 = 320,000/(1.0714) + 450,000/(1.0714)^2 + 680,000/(1.0714)^3 + 745,000/(1.0714)^4 + 795,000/(1.0714)^5 + 100,000/(1.0714)^6 + 10$

 $1,150,000/(1.0714)^6 + 17,507,002.80/(1.0714)^6$

= \$14,706,924.86

So the maximum purchase price of the Xi'An outlet would be \$14,706,924.86

c) The constant cash flow each year would give the same price for each of the retail outlets as was calculated in part b) is a perpetuity calculation.

Nanjing Outlet:

\$13,599,858.88 = A/0.0718

A = \$976.469.87

Xi'An Outlet:

\$14,706,924.86 = A/0.0714

A = \$1,050,074.44

Thus the Xi'An store generates the highest equivalent annual cash flow.

d) Given those purchase prices the 'wealth' created by each outlet would be:

Nanjing Outlet:

\$13,599,858.88 - \$13,500,000 = \$599,858.88

Xi'An Outlet:

14,706,924.86 - 14,800,000 = -93,075.14

So XHZ Ltd should purchase the Nanjing store as it is the only one which will increase the firm's wealth.

- 38) Calculate the present value of each option, and choose the one with the highest present value. Option 1 has a present value of \$100,000 (given); option 2 has a present value of \$10,000/0.12 = \$83,333; option three has a present value of \$50,000 + \$150,000[(1-(1+0.12)-10]/0.12 = \$98,300. Therefore the highest present value, and thus the best option to choose, is option 1: take the \$100,000 today.
- 39) You must make an initial payment of \$10,000 plus a series of annuity payments of \$800 per month for 48 months. The present value of the annuity is:

The monthly interest rate will be 12/12 or 1%

```
\$800 [1 - (1 + 0.01)^{-48}]/0.01 = \$30,379.17
```

Therefore the effective cost of the car will be \$30,379.17 + \$10,000 = \$40,379.17

- 40) Determine the effective simple interest equivalent of each accounts interest rate and compare them. Account A is giving the depositor an effective simple interest rate of 5.06% [EAR = $(1 + 0.05/2)^2 1$] whilst Account B is offering the depositor an effective interest rate of 4.99% [EAR = $(1 + 0.049/4)^4 1$]. Hence Account A will yield the highest future value for the depositor.
